Execution Report

Executive Summary

Intent: What is the weather like today?

Plan Overview

- 1. Search for reliable and free weather APIs that provide current weather data, including temperature, conditions, and location-based information. Identify at least two options, noting their API documentation and any rate limits or usage restrictions.
- 2. Create a project directory named 'weather_app' and initialize a Git repository within it. Also, create a subdirectory named 'src' inside 'weather_app'.
- 3. Develop a Python script named 'weather.py' inside the 'src' directory. This script should: 1. Import the 'requests' module. 2. Use the selected weather API to fetch weather data based on a user-provided location (e.g., city name). 3. Parse the API response (likely JSON format) to extract relevant weather information such as temperature, condition, and a brief description. 4. Display the weather information to the user in a clear and readable format. Include error handling for invalid locations or API request failures. 5. Save the file.
- 4. Review the created weather application and its functionality, ensuring that it correctly fetches, parses, and displays weather information. No action required.
